

Eating disorders and looking after your teeth

Eating disorders can cause permanent dental and oral health problems. It is important to seek professional advice from a dentist if you have concerns about your dental health or someone else's. It is better to see your dentist as soon as you can, so an oral care plan can be recommended.

Common signs and symptoms of dental problems associated with eating disorders

Dental erosion is a common sign in people with eating disorders. Erosion is the loss of tooth mineral due to the chemical attack of acids. It is commonly seen on the back surfaces of the upper front teeth in patients with bulimia nervosa. This can result in the tooth being sensitive to hot and cold and in some cases may result in more severe pain.

A low intake of water may result in poor quality saliva which fails to protect the teeth adequately compared to well hydrated saliva. Poor intake of vitamins may lead to infections at the corners of the mouth known as angular cheilitis or inflammation of the tongue called glossitis.

People with eating disorders may experience dry or cracked lips and a dry or burning sensation in the mouth.

Long-term dental problems

Your teeth are primarily made up of two hard materials – dental enamel and dentine. The dental enamel is the hard, translucent and highly mineralised outer layer of the tooth. Dentine is a less well

mineralised tissue that forms the bulk of the tooth. This inner material protects the blood vessels and nerves inside the tooth. Dentine is not as strong as enamel and when exposed to the oral environment is dissolved more easily by acid and is more prone to tooth wear.

In people with long term eating disorders the enamel on certain teeth surfaces can be completely dissolved and may expose the dentine which can then dissolve and wear more quickly. This may result in the nerve inside the tooth being exposed which may require a root canal filling or extraction. The loss of tooth height may also require dental treatment to restore the appearance and function of teeth.

People with anorexia may suffer from osteoporosis which can weaken the jaw bone, leading to weakened teeth and potentially tooth loss.

Should I tell my dentist about my eating disorder?

Yes, if you have an eating disorder you should discuss this with your dentist so that an oral care plan can be developed to limit the damage to the teeth. Dentists, like doctors, will deal with these issues in a non-judgemental and confidential manner.

Any general dentist is able to help, although in some cases you may be referred to a specialist.

Recommended dental products to use

In general, you should use a normal fluoridated toothpaste; however in some

cases a dentist may prescribe toothpaste with higher fluoride to increase the protection of your teeth. A fluoride mouth rinse may also be recommended for some people.

Tooth Mousse™ is a crème made from milk that contains calcium and phosphate and can help repair acid damage to the teeth and help neutralise acids. People with milk protein allergies should not use it. Tooth Mousse™ can be purchased from your dentist.

Helpful hints

During the process of vomiting, acid from the stomach flows over the teeth. This acid can dissolve the mineral that makes up our teeth. Some of the outer mineral will dissolve completely but a layer of softened mineral will also remain. This softened mineral can be rehardened by saliva and Tooth Mousse™.

One helpful hint is to not brush your teeth after vomiting as the softened enamel or dentine is weak immediately after vomiting and your toothbrush can wear it away and cause further damage. Instead, immediately after vomiting it is better to try and neutralise the acids. This can be done in one of two ways.

A teaspoon of sodium bicarbonate (a regular household cooking ingredient – bicarb soda) can be dissolved in water and used to rinse the mouth. This will neutralise any remaining acids and prevent them from damaging the teeth any further.

Rubbing Tooth Mousse™ around the teeth after vomiting is also beneficial. This will help neutralise the acids and provide calcium and phosphate to reharden the enamel.

Chewing sugar free chewing gum can also be useful in promoting saliva flow which provides natural calcium and phosphate to repair acid damage to the teeth.

It may also be helpful to avoid citrus fruit, fruit drinks, energy drinks and soft drinks.
